

PHP Magic Methods - Short Summary

Magic Methods are special methods in PHP that always start with two underscores (`__`). PHP calls them automatically when specific events occur in a class.

`__construct()`

Called automatically when an object is created. Used to initialize object properties.

`__destruct()`

Called automatically when an object is destroyed or the script ends. Used to release resources.

`__toString()`

Called when an object is printed with echo. Must return a string.

`__get()`

Called when accessing an inaccessible or undefined property.

`__set()`

Called when assigning a value to an inaccessible or undefined property.

`__call()`

Called when invoking an inaccessible or undefined method.

Conclusion: The most important Magic Method for beginners is `__construct()`, because it is used to initialize objects when they are created.
